Time Domain

Frequency Domain

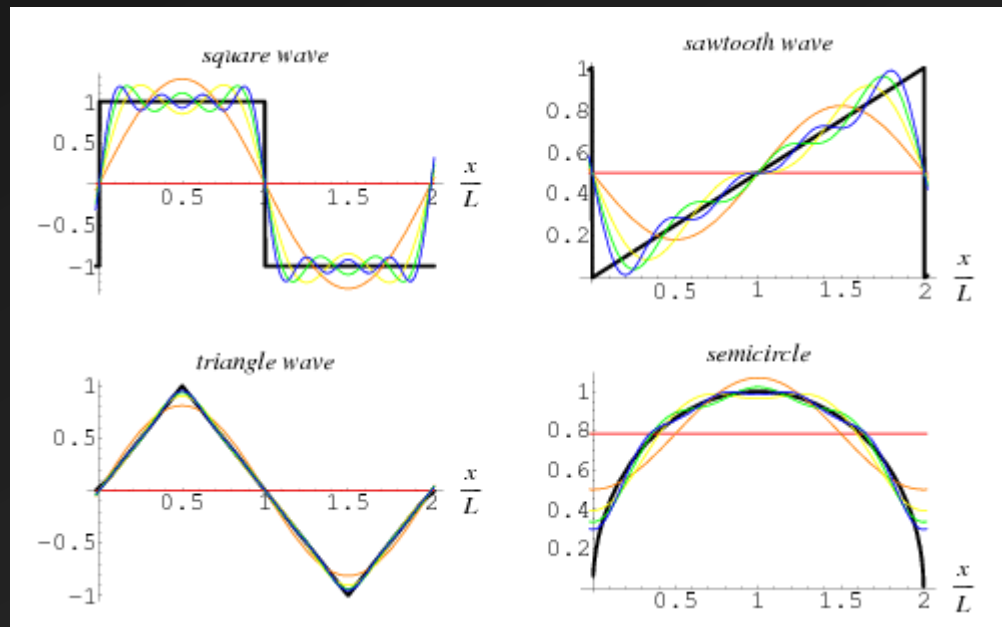

Figure 9: Constructing a complex signal from the superposition of sinusoids (top). The power spectrum of the signal show distinct peaks at the frequencies of the component sinusoids. A single sinusoid corresponds to a single peak in the power spectrum (bottom).

Fourier Series Representation

- If a signal is periodic, the signal can be expressed as the sum of sine and cosine waves of different amplitudes and frequencies
- This is known as the Fourier Series Representation of a signal

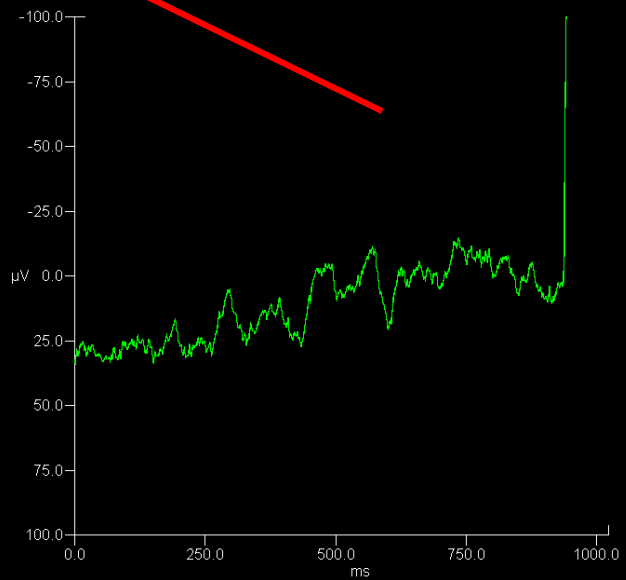

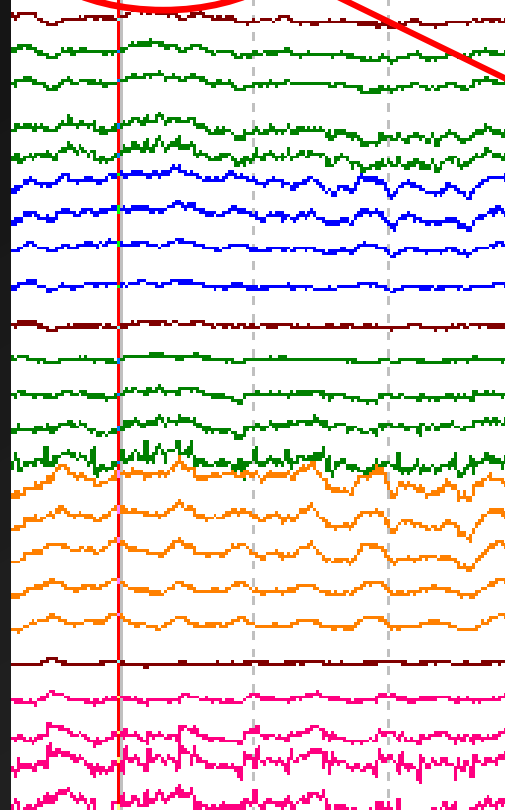

Fourier Series Representation

- Pragmatic Details
 - Lowest Fundamental Frequency is $1/T$
 - Resolution is $1/T$
- Phase and Power
 - There exist a phase component and an amplitude component to the Fourier series representation
 - Using both, it is possible to completely reconstruct the waveform.

Pragmatic Concerns

- Sample fast enough so no frequencies exceed Nyquist
 - signal bandwidth must be limited to less than Nyquist
 - Violation = **ERROR**
- Sample a long enough epoch so that lowest frequency will go through at least one period
 - Violation = **ERROR**
- Sample a periodic signal
 - if subject engaging in task, make sure that subject is engaged during entire epoch
 - Violation = ??, probably introduce some additional frequencies to account for change

Demo of EEG Data

- CNT Data to Frequency Domain Representation

*Frequency-domain EEG applications and
methodological considerations*

Applications

- Emotion Asymmetries
 - Lesion findings
 - Catastrophic reaction (LH)
 - RH damage show a belle indifference
 - EEG studies
 - Trait (150+ studies)
 - State (oodles more studies)

Types of Studies

➤ Trait

- Resting EEG asymmetry related to other traits (e.g. BAS)
- Resting EEG asymmetry related to psychopathology (e.g. depression)
- Resting EEG asymmetry predicts subsequent emotional responses (e.g. infant/mom separation)

➤ State

- State EEG asymmetry covaries with current emotional state (e.g., self report, spontaneous emotional expressions)

For reviews:

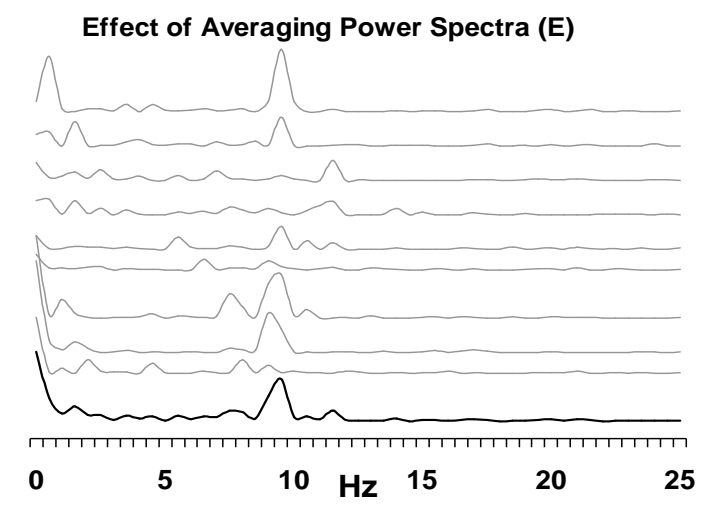

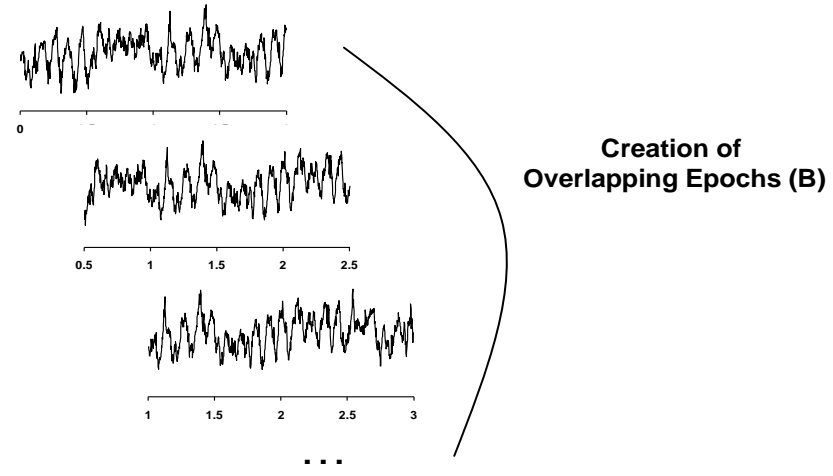

Allen, Coan, & Nazarian 2004

Allen & Reznik, 2015

Reznik & Allen, 2018

Trait, Occasion, and State variance

- Three sources of reliable variance for EEG Asymmetry
 - *Stable trait consistency* across multiple assessments
 - *Occasion-specific* variance
 - reliable variations in frontal asymmetry across multiple sessions of measurement
 - may reflect systematic but unmeasured sources such as current mood, recent life events and/or factors in the testing situation.
 - *State-specific* variance
 - changes within a single assessment that characterize
 - the difference between two experimental conditions
 - the difference between baseline resting levels and an experimental condition.
 - conceptualized as proximal effects in response to specific experimental manipulations
 - should be reversible and of relatively short duration
- Unreliability of Measurement (small)

Alpha Vs Activity Assumption (AAA)

Alpha and Activity

- May be more apt to think of alpha as regulating network activity
- High alpha has inhibitory function on network activity (more in advanced topics)

EEG Asymmetry, Emotion, and Psychopathology

1978

EIGHTEENTH ANNUAL MEETING SOCIETY FOR PSYCHOPHYSIOLOGICAL RESEARCH

The Eighteenth Annual Meeting of The Society for Psychophysiological Research was held at The Concourse Hotel in downtown Madison, Wisconsin, September 15, 16, 17, and 18, 1978. Members of the Program Committee were: Rafael Klorman and Ted Weerts (Co-Chairmen), Michael Coles, Don Fowles, Linda Gannon, James Leon J. Richard, Jennings, Rathe Karrer, Michael Nelson, Arne Öhman, Leonard Salzman, and David Siddall.

As in recent years, the bulk of the research reports were given and discussed informally at Friday and Sunday evenings, September 15 and 17. In addition, research reports were presented in sessions on Saturday and Monday mornings, and others were included in the Display and Discussion sessions which ran in tandem with the meetings on Saturday from 8:30 to 5:00. Several symposia, workshops were also included in this year's program.

Following are the abstracts of research reports presented and discussed during the Paper Session, Display and Discussion poster session.

PAPER SESSION II

I. Silverstein, L. D., & Graham, F. K. (University of Wisconsin - Madison) Selective attention effects on reflex activity. Bohlin and Graham (1977) found that reflex blinking, unlike spontaneous blinking, was facilitated in association with cardiac deceleration when subjects were required to attend to the reflex-eliciting stimulus. The enhancement of sensory processing on the attended channel was proposed as an explanation for the facilitation. If so, directing attention to a different channel should remove the facilitation. This hypothesis was tested in two experiments analogous to the Bohlin and Graham (1977) studies. The critical change was requiring subjects to attend to a stimulus in a modality orthogonal to that of the reflex-eliciting stimulus.

In each experiment, 15 college students received 60- or 120-msec, low-intensity, electrocutaneous stimuli concurrently with a 50-msec auditory startle pulse. A warning tone preceded electrocutaneous and startle stimuli by 2 sec in the experimental conditions, while in the control conditions the two stimuli were presented without warning. Subjects' task was to discriminate electrocutaneous stimulus duration.

As in earlier intramodal studies, the warning tone elicited significant cardiac deceleration during the warning intervals of both experiments. Significantly better discrimination occurred on warned than unwarned control trials (Exp. 1—73.7% vs 60.3%; Exp. 2—73.2% vs 49.5%). Reflex blink latency was also significantly facilitated in both experiments. However, unlike the intramodal studies, blink magnitude was reduced. A small reduction in Experiment 1 was not a reliable effect, but increased startle pulse intensity in Experiment 2 resulted in a larger and significant reduction.

The hypothesis that reflexive motor activity is influenced by selective sensory enhancement was closely supported. The results are interpreted with respect to a general theory of orienting and reflex control.

(Supported by the Grant Foundation, by an NSF grant BMS75-17075, and by a Research Scientist Award K3-MH21762 and a Fellowship Award MH07198-01 from NIMH)

2. Washon, A. M. (New York Medical College) Autonomic and stimulus control of conditional cardiac rate responses in rhesus monkeys. Conditional cardiac rate responses (cardiac CRs) of 6 rhesus monkeys were examined under systematic and broad manipulation of the temporal variable of CS-US interval length. A Pavlovian delay conditioning procedure was employed in which the duration of a visual conditional stimulus (CS) preceding an aversive electric-shock unconditional stimulus (US) was increased progressively from 2 to 120 sec for each animal. At each of 8 differing CS-US interval conditions, selective autonomic blocking agents were administered to assess the relative roles of the sympathetic and parasympathetic branches of the autonomic nervous system in the elaboration of observed cardiac rate CRs. Each subject was tested both in the absence of any drugs and under: 1) sympathetic blockade with propranolol, 2) parasympathetic blockade with atropine, 3) double blockade with a

combination of propranolol and atropine, and 4) ganglionic blockade with chlorisondamine.

The within-CS waveform of the cardiac rate CR was least consistent at the first 3 CS-US intervals of 2-6 sec, where instances of accelerative, decelerative, and biphasic HR patterns were observed during CS both within and among subjects, with the direction of response varying with the level of HR just prior to CS onset. By contrast, at CS-US intervals from 10 to 120 sec, a stable and consistent biphasic HR pattern of initial acceleration followed by deceleration was uniformly observed during CS despite continued wide fluctuations in pre-CS HR.

Both accelerative and decelerative HR changes within the CS-US interval were eliminated almost entirely by parasympathetic blockade alone, combined sympathetic and parasympathetic blockade, and ganglionic blockade. Sympathetic blockade alone left large HR changes within the CS-US interval, with CR deceleration often facilitated relative to pre-drug. These effects were similar across the full range of CS-US intervals employed, and whether the pre-drug form of the cardiac CR was monophasic or biphasic. The unconditional HR response (UCR) to shock was similar in form to the CR, consisting of an initial accelerative and subsequent decelerative component, and was similarly affected by the pharmacological agents, although the UCR was less suppressed by the drugs.

3. Davidson, R. J. (State University of New York at Purchase), Schwartz, G. E. (Yale University), Saron, C., Bennett, J. (State University of New York at Purchase), & Goleman, D. J. Frontal versus parietal EEG asymmetry during positive and negative affect. A variety of data suggest that positive and negative affect may be differentially lateralized in the human brain. This

report describes an experiment which explored the differential effect of positive versus negative affect on parietal and frontal brain regions. Seventeen right-handed subjects were exposed to portions of a television show judged to vary in emotional content. Subjects were asked to press down on a pressure-sensitive knob according to how much they disliked and to let up according to how much they liked the program, with hand use counterbalanced across subjects. These pressure changes, along with EEG filtered for 8-13 Hz recorded from F₄, F₃, F₂, F₁ and P₃ referenced to C_z were digitized and printed every 30 sec. Two epochs representing the most positively and most negatively judged segments were chosen for analysis on the basis of each subject's ratings and were compared on parietal and frontal asymmetry as reflected in the ratio R-L/R+L alpha. The results revealed a significant Region (Frontal vs Parietal) × Affective Valence (positive vs negative) interaction. During positive affect, the frontal leads display greater relative left hemisphere activation compared with negative affect and vice versa. Parietal asymmetry does not discriminate between these conditions, but does show right hemisphere activation during both.

A second experiment was conducted (Schwartz, Davidson, & Saron) during which self-generated positive and negative affective imagery served as the main inde-

Individual Subjects' Data

Valence Vs Motivation

- Valence hypothesis
 - Left frontal is positive
 - Right frontal is negative
- Motivation hypothesis
 - Left frontal is Approach
 - Right frontal is Withdrawal
- Hypotheses are confounded
 - With possible exception of Anger

Correlation with alpha asymmetry ($\ln[\text{right}] - \ln[\text{left}]$) and trait anger. Positive correlations reflect greater left activity (less left alpha) is related to greater anger.

After Harmon-Jones and Allen (1998).

State Anger and Frontal Asymmetry

- Would situationally-induced anger relate to relative left frontal activity?

Method

- Cover story: two perception tasks – person perception & taste perception
- Person perception task – participant writes essay on important social issue; another ostensible participant gives written feedback on essay
- Feedback is neutral or insulting
 - negative ratings + “I can’t believe an educated person would think like this. I hope this person learns something while at UW.”

- Record EEG immediately after feedback
- Then, taste perception task, where participant selects beverage for other participant, “so that experimenter can remain blind to type of beverage.”
- 6 beverages; range from pleasant-tasting (sweetened water) to unpleasant-tasting (water with hot sauce)
 - Aggression measure

Harmon-Jones & Sigelman, *JPSP*, 2001

Relative Left Frontal, Anger, & Aggression as a Function of Condition

Frontal EEG asymmetry predicts Anger and Aggression

- Not in Neutral condition ... no relationship
- Strongly in Insult condition
 - $r = .57$ for anger
 - $r = .60$ for aggression
 - Note: partial r adjusting for baseline indiv diffs in asymmetry and affect

Manipulation of EEG

Peterson, Shackman, Harmon-Jones (2008)

- Hand contractions to activate contralateral premotor cortex
- Insult about essay (similar to Harmon-Jones & Sigelman, *JPSP*, 2001) followed by chance to give aversive noise blasts to the person who insulted them
- Hand contractions:
 - altered frontal asymmetry as predicted
 - Altered subsequent aggression (noise blasts)
- Asymmetry during hand contractions predicted aggression

Figure 1. Relation between noise length and frontal-central asymmetry during right-hand contractions. Higher asymmetry scores indicate greater relative left than right activation.

The BAS/BFS/Approach System

- **sensitive to signals of**
 - **conditioned reward**
 - **nonpunishment**
 - **escape from punishment**

Replications

Sutton & Davidson, 1997

Coan & Allen, 2003

Correlations with alpha asymmetry ($\ln[\text{right}] - \ln[\text{left}]$) and self-reported BAS scores (right) or BAS-BIS (left).

Positive correlations reflect greater left activity (less left alpha) is related to greater BAS scores or greater BAS-BIS difference

L>R Activity (R>L Alpha) characterizes:

- an approach-related motivational style (e.g. Harmon-Jones & Allen, 1997; Sutton & Davidson, 1997)
- higher positive affect (e.g. Tomarken, Davidson, Wheeler, & Doss, 1992)
- higher trait anger (e.g. Harmon-Jones & Allen, 1998)
- lower shyness and greater sociability (e.g. Schmidt & Fox, 1994; Schmidt, Fox, Schulkin, & Gold, 1999)

R>L Activity (L>R Alpha) characterizes:

- depressive disorders and risk for depression (e.g. Allen, Iacono, Depue, & Arbisi, 1993; Gotlib, Ranganath, & Rosenfeld, 1998; Henriques & Davidson, 1990; Henriques & Davidson, 1991 **but see also Reid, Duke, & Allen, 1998**)
- certain anxiety disorders (e.g. Davidson, Marshall, Tomarken, & Henriques, 2000; Wiedemann et al., 1999)

Correlations \neq Causality

- Study to manipulate EEG Asymmetry
- Five consecutive days of biofeedback training (R vs L)
 - Nine subjects trained “Left”; Nine “Right”
 - Criterion titrated to keep reinforcement equal
- Tones presented when asymmetry exceeds a threshold, adjusted for recent performance
- Films before first training and after last training

Training Effects: Asymmetry Scores

Manipulation of EEG asymmetry with biofeedback produced differential change across 5 days of training; Regression on Day 5

From Allen, Harmon-Jones, and Cavender (2001)

Despite no differences prior to training, following manipulation of EEG asymmetry with biofeedback subjects trained to increase left frontal activity report greater positive affect.

From Allen, Harmon-Jones, and Cavender (2001)

From Allen, Harmon-Jones, and Cavender (2001)

Manipulation of Asymmetry using Biofeedback

- Phase 1: Demonstrate that manipulation of EEG asymmetry is possible
- Phase 2: Determine whether EEG manipulation has emotion-relevant consequences
- Phase 3: Examine whether EEG manipulation produces clinically meaningful effects
- Phase 4: Conduct efficacy trial

Phase 3a

Biofeedback provided 3 times per week for 12 weeks

Phase 3b

“Open Label” pilot trial, with biofeedback provided 3 times per week for 12 weeks

Phase 4: Randomized Control Trial

- Depressed subjects ages 18-60 to be recruited through newspaper ads
- Ad offers treatment for depression but does not mention biofeedback
- Participants meet DSM-IV criteria for Major Depressive Episode (nonchronic)

Design

- Contingent-noncontingent yoked partial crossover design
- Participants randomly assigned to:
 - *Contingent Biofeedback*: tones presented in response to subject's EEG alpha asymmetry
 - *Noncontingent Yoked*: tones presented that another subject had heard, but tones not contingent upon subject's EEG alpha asymmetry
- Treatments 3 times per week for 6 weeks
- After 6 weeks, all subjects receive contingent biofeedback 3 times per week for another 6 weeks

Results

Dropout rate > 70%!

States – how short can they be?

A better estimate of the internal consistency reliability of frontal EEG asymmetry scores

DAVID N. TOWERS AND JOHN J.B. ALLEN

Department of Psychology, University of Arizona, Tucson, Arizona, USA

Abstract

Frontal alpha asymmetry is typically computed using alpha power averaged across many overlapping epochs. Previous reports have estimated the internal consistency reliability of asymmetry by dividing resting EEG sessions into segments of equal duration (e.g., 1 min) and treating asymmetry scores for each segment as “items” to estimate internal consistency reliability using Cronbach’s alpha. Cronbach’s alpha partly depends on the number of items, such that this approach may underestimate reliability by using less than the number of distinct items available. Reliability estimates for resting EEG data in the present study (204 subjects, 8 sessions) were obtained using mean split-half correlations with epoch alpha power as treated as separate items. Estimates at all scalp sites and reference schemes approached .90 with as few as 100 epochs, suggesting the internal consistency of frontal asymmetry is greater than that previously reported.

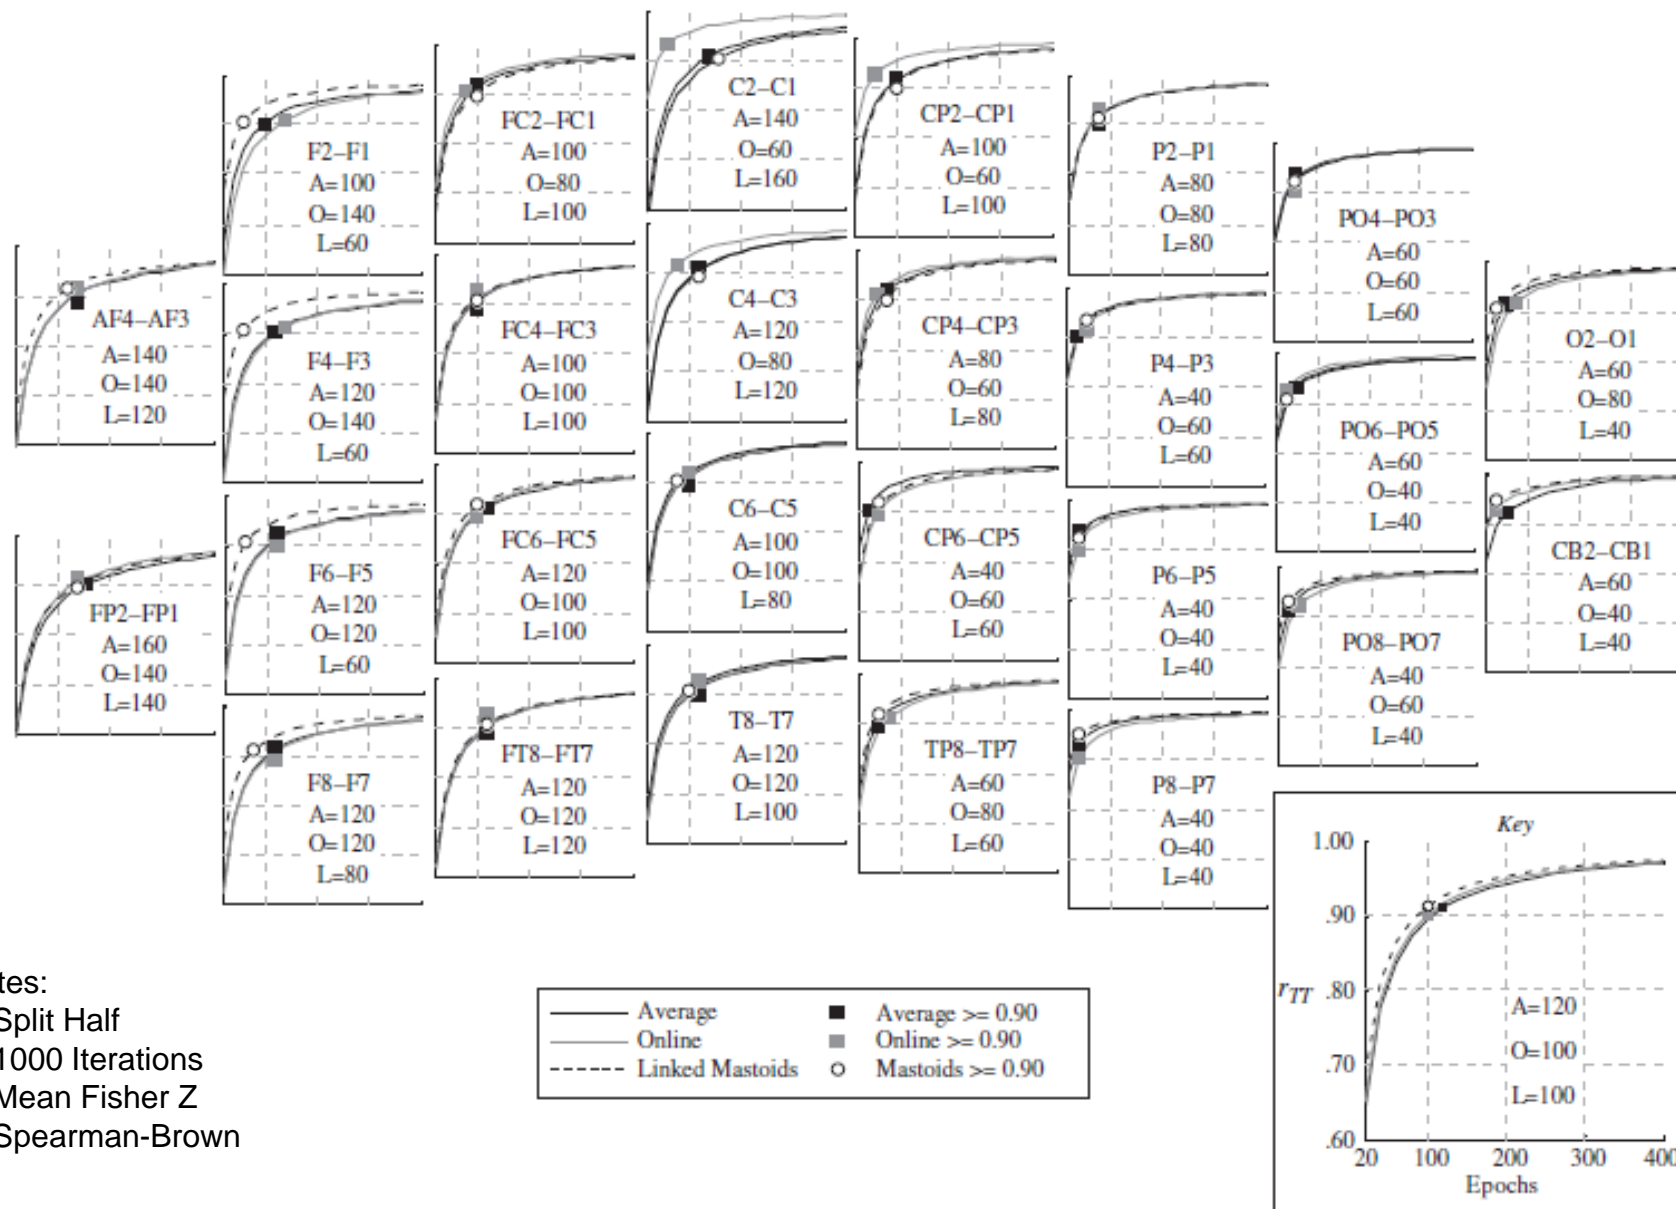

Figure 1. Estimated internal consistency reliability (r_{TT}) of asymmetry scores for epoch set sizes n ranging from 20 to 400, across average (black), online (gray), and linked-mastoids (dashed) reference derivations and all homologous electrode pairs. Graph markers and table insets indicate the epoch set size n at which the estimated internal consistency reliability coefficient for each reference derivation was greater than or equal to .90.

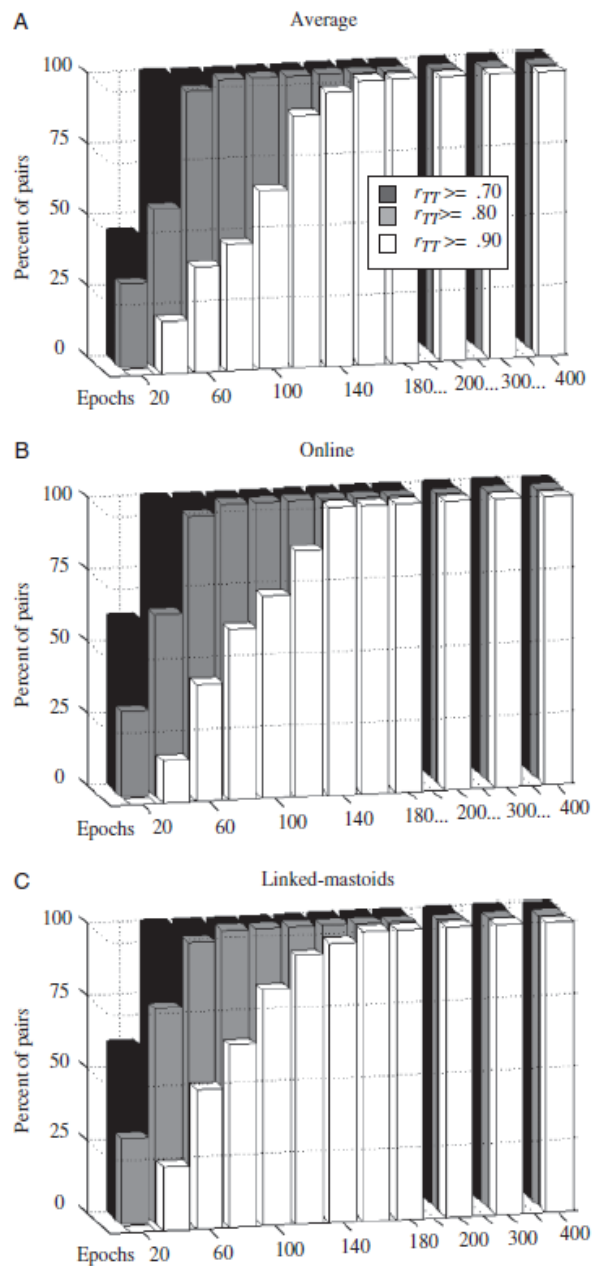

Figure 2. Percentage of homologous electrode pairs in which estimates of internal consistency reliability (r_{TT}) of asymmetry scores were greater than or equal to .70 (white), .80 (light gray), and .90 (dark gray) as a function of epoch set size n and reference derivation.

Figure 3. Estimated internal consistency reliability (r_{TT}) of asymmetry scores for epoch set sizes of 120 and 200, with light gray numbers indicating $.85 \leq r_{TT} < .90$ and bold numbers indicating $r_{TT} \geq .95$ (the pair CB2-CB1 was omitted).

State EEG in CIT!

Fig. 2. Grand average frontal EEG asymmetry scores for target, critical, and non-critical items in the guilty and innocent condition. Asymmetry score = $\ln[\text{F4 alpha power}] - \ln[\text{F3 alpha power}]$. Bars depict standard errors. * $p < .05$.

Resting brain asymmetry as an endophenotype for depression

Endophenotypes

- Intermediate-level measure of characteristics related to risk for disorder
- Less complex phenotype for genetic association
- Can include, biochemical and imaging measures, among others
- Desiderata
 - Specificity
 - Heritability
 - State-independence
 - Familial Association
 - Co-segregation within families
 - Predicts development of disorder

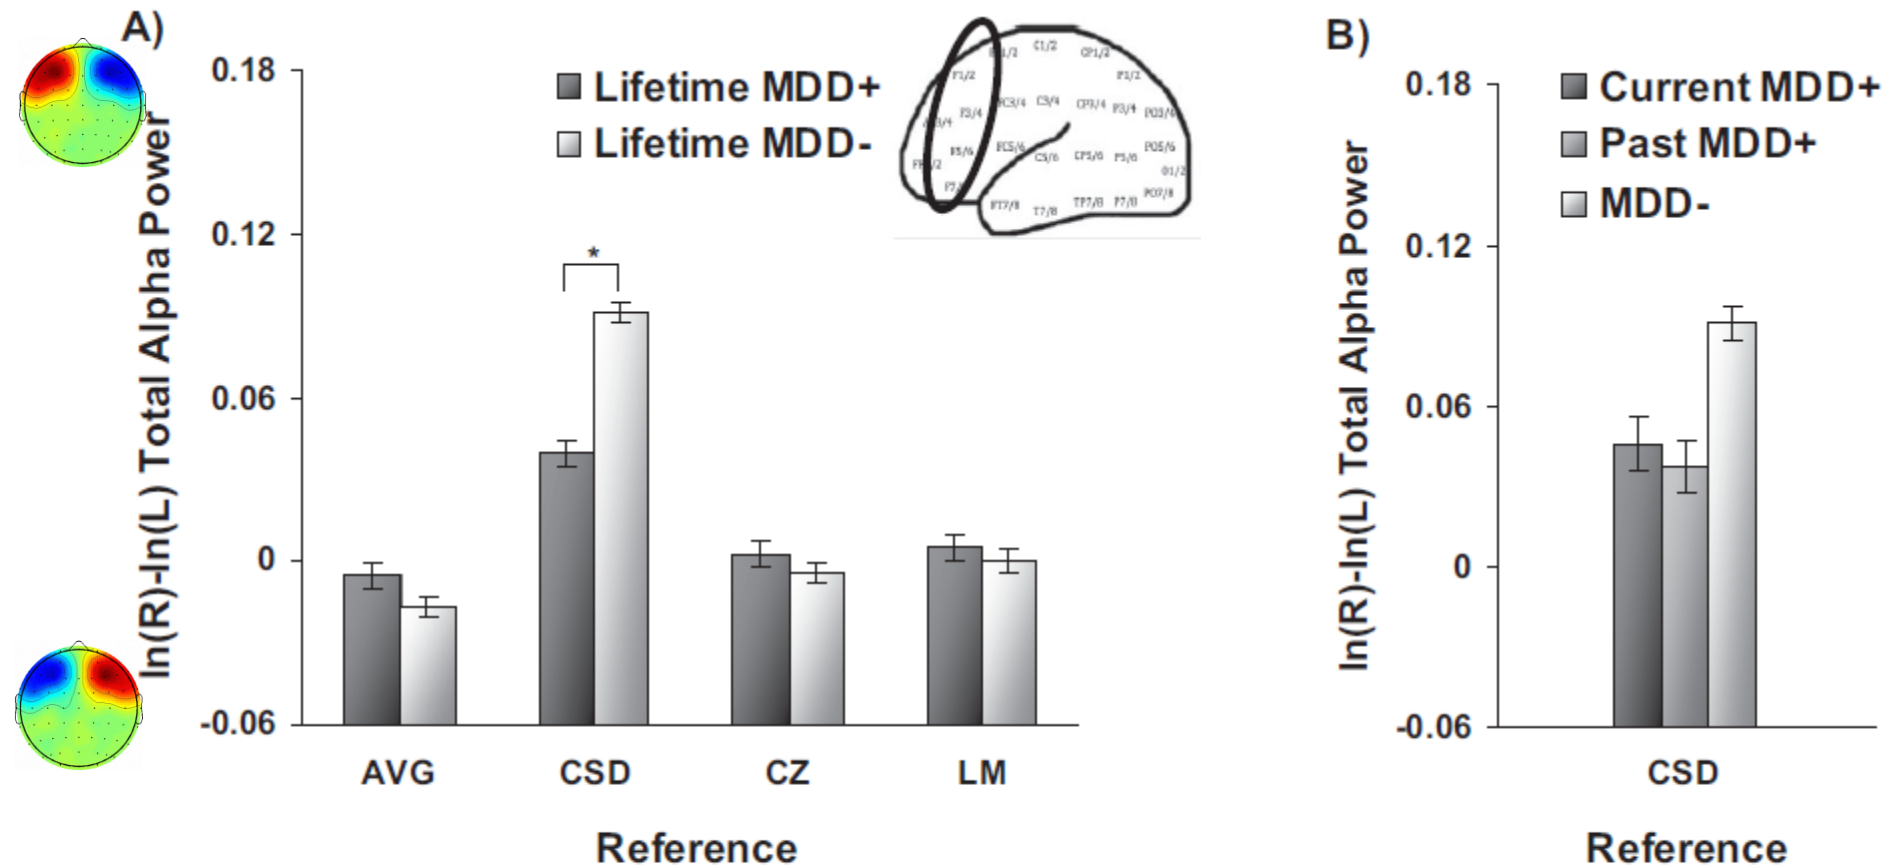

Figure 2. Panel A shows frontal alpha asymmetry scores (8–13 Hz at F2–F1, F4–F3, F6–F5, F8–F7) by lifetime MDD status for each reference montage across all four frontal regions depicted on the head insert. Error bars reflect standard error. Panel B shows results of a follow-up assessment indicating that the relationship of lifetime MDD status to CSD-referenced asymmetry is not solely accounted for by current MDD status. The y-axis is $\ln \mu V^2$ for AVG, Cz, and LM references, and $\ln \mu V^2/cm^2$ for CSD referenced data. MDD = major depressive disorder; AVG = average; CSD = current source density; CZ = Cz; LM = linked mastoid.

STICK WITH CSD...

Interim Synopsis: Endophenotype Desiderata

Gottesman & Shields, 1972; Gottesman & Gould, 2003; Iacono, 1998

- ☑ Specificity: Associated with disorder
- ☑ Heritability
- ☑ State-independence: Primarily trait
- ☑ Familial Association: Seen in unaffected family members at rates higher than general population
- ◄ Predictive Power: predicts future disorder in unaffected individuals

Prospective Pilot Data

- ◆ Assessed never depressed (MDD-) individuals ~1 year after EEG
- ◆ Obtained 54 of 163 (representative)
- ◆ Completed BDI based on “worst month”
- ◆ BDI worst month residualized on BDI at EEG assessment
- ◆ Can EEG predict this worst month BDI score?

Prospective Pilot Data

See also Nusslock et al.,
J Abnormal Psychology,
2011

Prospective Pilot Data: a wrinkle

Thus

- ◆ Frontal EEG asymmetry has promise as a risk indicator for MDD and other internalizing disorders
- ◆ Need:
 - ◆ Large-scale prospective study
 - ◆ Links to underlying neural systems

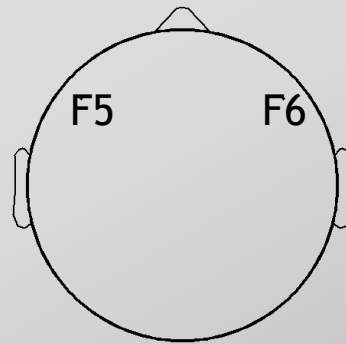

TIME AND SPACE

Deconstructing the “resting”
state:

Exploring the temporal dynamics
of resting frontal brain
asymmetry as an endophenotype
for depression

The Conventional Approach

- ◆ One number to summarize several minutes of resting data
- ◆ Good reliability, but...
 - ◆ Lacks temporal specificity
 - ◆ Confuses “more” with “more often”

$$\text{Asym} = \text{Ln}(\text{Right}) - \text{Ln}(\text{Left}) \text{ Alpha Power}$$

Difference

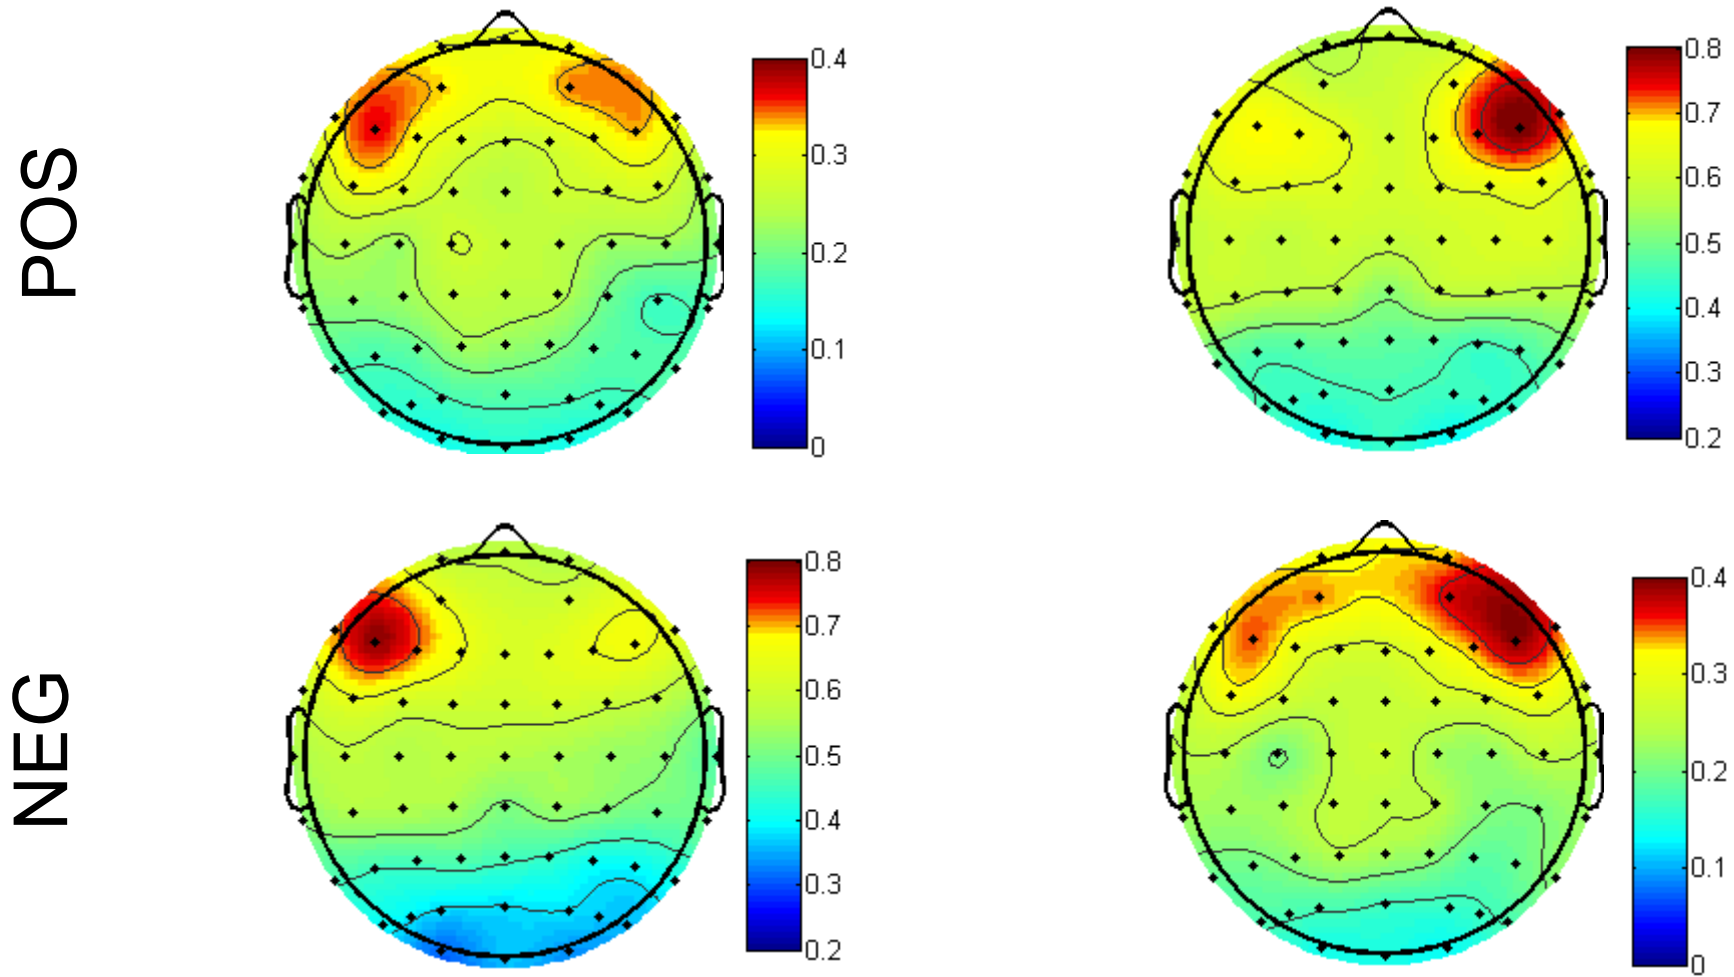

Three Central Questions

- ◆ How do the novel peri-burst metrics of dynamic asymmetry compare to the conventional FFT-based metrics?
- ◆ Do the peri-burst metrics adequately differentiate depressed and non-depressed participants
- ◆ What EEG dynamics surround the asymmetry bursts that are captured by the novel peri-burst metrics?

Three Central Questions

- ◆ How do the novel peri-burst metrics of dynamic asymmetry compare to the conventional FFT-based metrics?
- ◆ Do the peri-burst metrics adequately differentiate depressed and non-depressed participants
- ◆ What EEG dynamics surround the asymmetry bursts that are captured by the novel peri-burst metrics?

Relationship of Peri-Burst Alpha Power with Conventional FFT-Derived Power

Peri-burst time (ms)

Allen & Cohen, 2010

So?

- ◆ Novel peri-burst metrics account for substantial variance in conventional metrics (despite being just 1%)
- ◆ Peri-burst metrics differentiate depressed and non-depressed participants, similar to conventional metrics

So?

- ◆ Bursts reflect ...

- ◆ Transient lateralized alpha suppression that shows a highly consistent phase relationship across bursts

- ◆ Along with concurrent contralateral transient alpha enhancement that is less tightly phase-locked across bursts

- ◆ Analogous to ERD/ERS (Pfurtscheller, 1992)?

So?

- ◆ The fact that the alpha suppression is particularly tightly phase-locked across bursts raises the possibility that the lateralized alpha suppression may drive or regulate cortical processing
- ◆ Alpha has been shown to regulate gamma power (i.e., cross-frequency coupling, Cohen et al., 2009)

TIME AND SPACE

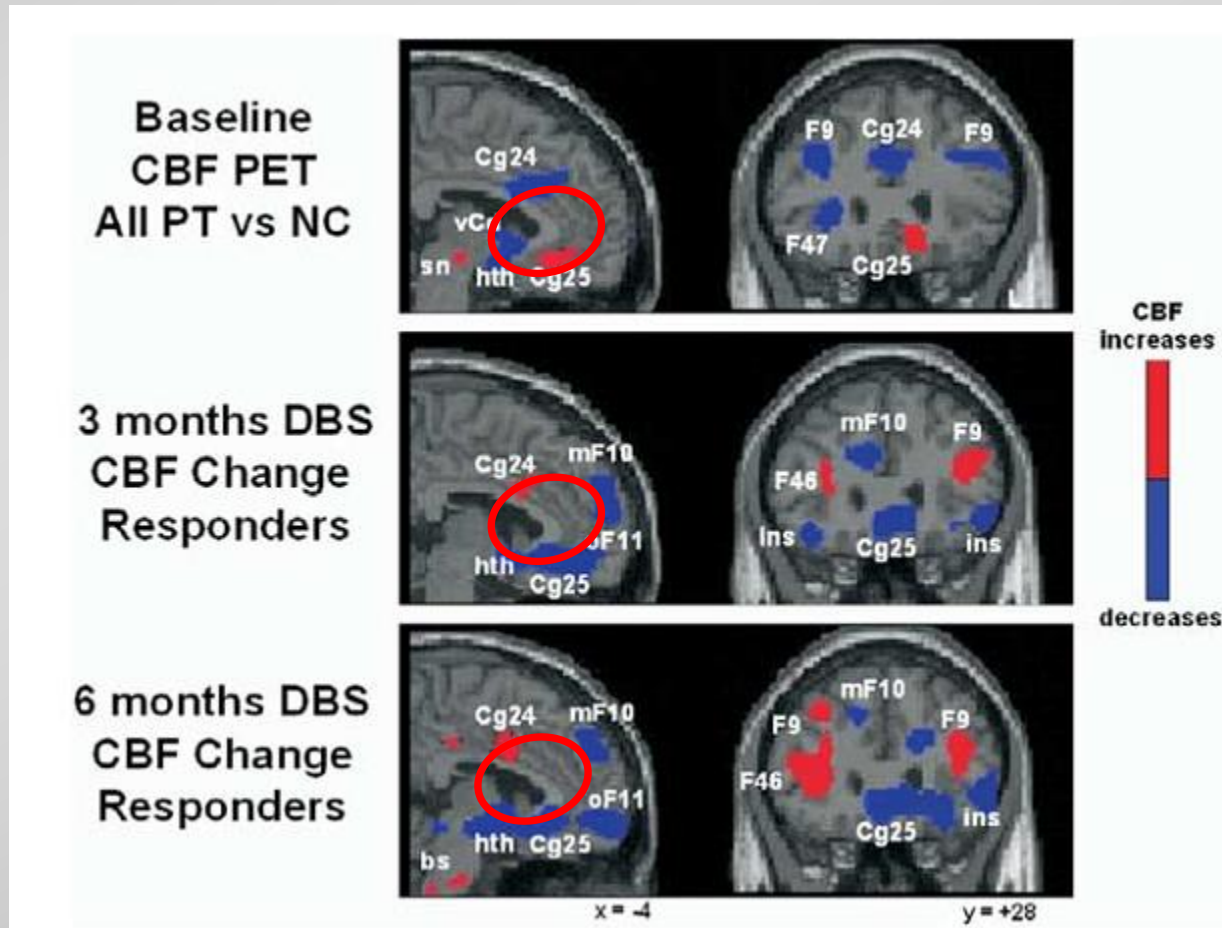

Multi-modal Imaging

- ◆ Tether EEG asymmetry to other measures neural systems known to be involved in MDD
- ◆ 23 subjects with simultaneous EEG and fMRI during resting state

Multi-modal Imaging

- ◆ Tether EEG asymmetry to other measures neural systems known to be involved in MDD

Multi-modal Imaging

- ◆ Create RS-fMRI network with ACC seeds

Remove Artifacts from Resting EEG

EEG Alpha Asymmetry is Negatively Correlated with IFG Connectivity in Two ACC-seeded Resting State Networks

Spatially-enhanced EEG asymmetry (using CSD transform) at sites F8-F7 is related to resting state connectivity between left inferior frontal gyrus and two ACC-seeded networks.

Dorsal ACC-seeded Network

Center of the depicted cluster is (x,y,z) -46, 28, -4 MNI coordinates.

Largest correlation. $r = -0.69$

Subgenual ACC-seeded Network

Center of the depicted cluster is (x,y,z) -54, 28, -4 MNI coordinates.

Largest correlation. $r = -0.71$

EEG-fMRI Synopsis

- ◆ Less relative left frontal activity (indexed by EEG) is related to increased connectivity of left IFG to two ACC-seeded RS networks
- ◆ Consistent with:
 - ◆ Hyper-connectivity in RSfMRI emotion networks in MDD (e.g., Greicius et al., 2007; Sheline et al., 2010)
 - ◆ Frontal EEG asymmetry findings of less relative left frontal activity in risk for MDD.
- ◆ Alpha power may regulate network connectivity
 - ◆ Note: Between vs Within Subjects

BETWEEN-SUBJECTS' DATA DOES NOT NECESSARILY SUPPORT A WITHIN-SUBJECTS' INTERPRETATION

Within Subjects' Moderation of RSfMRI Connectivity

- ◆ Calculate F8-F7 alpha asymmetry for each TR
 - ◆ EEG leads TR by 4.096 seconds
- ◆ Median split into high (left) and low (right)
- ◆ Entered as moderator in PPI approach (cf. Friston et al., 1997)
 - ◆ Tests whether strength of connectivity to seed region varies as a function of the moderator

Within Subjects' Moderation of RSfMRI Connectivity

Dorsal ACC Seed

Greater Connectivity with
Less Left Frontal Alpha or
Greater Left Frontal Alpha

Within (red) and Between (blue)
Within-subject effects more extensive

Cognitive Control over Emotion

- ◆ IFG has a key role in mediating the success of cognitive control over emotional stimuli

Cognitive Control over Emotion

◆ Left IFG:
Language and
self-referential
processing

◆ Right IFG:
Attentional control

- ◆ behavioral inhibition
- ◆ suppression of unwanted thoughts
- ◆ attention shifting
- ◆ efforts to reappraise emotional stimuli

Cognitive Control over Emotion

◆ Left IFG:
Language and
self-referential
processing

◆ Right IFG:
Attentional control

- ◆ behavioral inhibition
- ◆ suppression of unwanted thoughts
- ◆ attention shifting
- ◆ efforts to reappraise emotional stimuli

◆ Working Hypothesis:

- ◆ Hyperconnected left IFG* and emotion networks:
rumination
- ◆ Hypoconnected right IFG: difficulty disengaging from emotion
